Nucleated red blood cell count in term and preterm newborns: reference values at birth

S Perrone, P Vezzosi, M Longini, B Marzocchi, D Tanganelli, M Testa, T Santilli, G Buonocore, on behalf of the Gruppo di Studio di Ematologia Neonatale della Società Italiana di Neonatologia

The prognostic value of nucleated red blood cell count at birth in relation to neonatal outcome has been established. However, reference values were needed to usefully interpret this variable. The normal range of reference values for absolute nucleated red blood cell count in 695 preterm and term newborns is reported.

Nucleated red blood cells (NRBCs) are immature erythrocytes, commonly found in the peripheral blood of newborns at birth. NRBC count varies widely at birth. Fetal hypoxia, the major risk factor for adverse perinatal outcome, has been claimed to induce a rise in the number of NRBCs.

Distinct NRBC patterns seem to be related to the timing of fetal injury, suggesting that NRBC count may assist in determining the timing of fetal neurological impairment as previously shown by us. High numbers of NRBCs reflect the severity and duration of hypoxia, and NRBC count may rise rapidly after brief but severe hypoxia, due to release of stored NRBCs.

Defining normal haematological values for newborns is problematical because the range of values in term or sick infants generally does not apply to preterm or healthy infants. Because of the lack of information on normal NRBC count in infants, we aimed to establish a normal reference range based on evaluation of a large number of neonates without clinical signs of perinatal hypoxia at birth or of any known disease recognised to affect the number of circulating NRBCs.

METHODS AND RESULTS

A total of 695 (455 preterm, consecutively delivered, and 240 term, randomly selected) babies were the subjects of our study.

Gestational age was determined from the last menstrual period and early ultrasonography; if there was any discrepancy, neonatal Dubowitz evaluation was used. All babies with congenital malformation, haematopoietic anomalies, Rh and/or ABO incompatibility, inborn error of metabolism, sepsis, a mother with diabetes, multiple gestation, smoking, drug abuse, anaemia, placenta previa, abruption, or infarcts were excluded from the study to eliminate risks that could affect the number of circulating NRBCs.

We also prospectively collected specific neonatal data: Apgar score at five minutes, birth weight, cord pH. After excluding neonates documented to have a five minute Apgar score <6, cord pH<7.2, birth weight more than 2 SDs below the mean, according to the growth chart of Yudkin et al, we identified those whom we designated as “normal”. A normal neonate was defined as one without maternal or intrapartum complications, who was also normal on physical examination at the time of blood sampling. The final study population included 695 babies. To exclude any effects of gestational age on NRBC count, the 695 newborns enrolled were divided into four groups according to gestational age (table 1). Informed consent was obtained from the mothers of all normal neonates. The protocol was approved by the human ethics committee of the Medical Faculty, University of Siena.

Heparinised blood samples were obtained from the umbilical vein, immediately after delivery. NRBC was expressed as absolute count (NRBC/mm³), calculated by light microscope examination of May-Grunwald-Giemsa stained blood smears.

Mean, median, and SD were calculated in each group. The Kolmogorov-Smirnov test rejected the hypothesis of normal distribution for all groups. Logarithmic transformation was not tried because zero values of NRBC could not be missed. We drew a right sided asymmetric interval. The 0.975 fractile with its 90% confidence interval was taken as the upper reference value. Spearman’s test was used to evaluate statistical correlations.

RESULTS

Table 1 shows a descriptive statistical analysis of each group. Table 2 reports upper reference value data. Figure 1 shows

| Table 1 | Birth weight and gestational age of the 695 newborns enrolled |
|-----------------|-----------------|-----------------|-----------------|
| Birth weight (g) | Mean (SD) | Median | 25th–75th centiles |
| Group 1 (n=120) | 954 (233.9) | 930 | 780–1105 |
| Group 2 (n=128) | 1413 (397.8) | 1360 | 1100–1720 |
| Group 3 (n=215) | 2189 (472.7) | 2235 | 1940–2520 |
| Group 4 (n=232) | 3201 (669.0) | 3210 | 2905–3590 |

NRBC count at birth in relation to gestational age by two
weekly intervals. As expected, absolute NRBC count
decreased with length of gestation and increasing birth
weight (p = −0.559, p<0.0001 and p = −0.546, p<0.0001
respectively).

DISCUSSION
Most of the articles on NRBC count at birth report NRBCs
relative to 100 white blood cells. Unfortunately, the vari-
ability of leucocyte count after birth results in a wide range of
values for NRBCs when expressed in this way. The problem is
magnified by the many pathological processes that signifi-
cantly alter total leucocyte count and lead to a misleadingly
low value of NRBCs per 100 white blood cells.

The aim of this study was to obtain absolute NRBC reference
values based on evaluation of a large number of
neonates. Cord blood at birth was used to ensure that the
values reasonably represented the effects of the intrauterine
environment.

As expected, absolute NRBC count decreased with advanc-
ing gestation and increasing birth weight. In a previous
study, we reported a normal NRBC range for preterm babies.2

count at birth in relation to gestational age.

confirmed by the range of the 90% confidence interval and
the small number of cases of our reference population not
included in the reference interval.

It is important to record and report normal and pathol-
ogical findings in newborn infants, especially when an
abnormally high NRBC count is found in the cord smear
and conversely when this count is not raised, which may be
just as important. Interesting cases include apparently
normal babies with an unusually high NRBC count. In these
cases, a normal reference value is useful for both medical and
legal purposes. Indeed, a high NRBC count in cord blood
strongly suggests an intrauterine hypoxic event several hours
before birth. This knowledge is extremely relevant not only as
an index of perinatal brain damage for medical use, but also
as an indication of the timing of the hypoxic event for legal
controversies.
