pulse, BP and baseline bloods (FBC, U&Es, Clotting, ABGs, G&S) monitored. Checking of capillary refill time (13.8%), administration of high-flow oxygen (12.5%), blood cultures (27.5%), electrocardiograms (37.5%) and fluid balance monitoring (56.3%-81.3%) need to be performed more frequently. 16 patients had SPE. Baseline bloods (FBC, U&Es, urate, LFTs & G&S), administration of ranitidine and catheterisation were performed in all patients. Of concern are: checking of clotting screen (87.5%), blood pressure monitoring after administration of antihypertensives (33.3%-46.2%) and observations after Magnesium sulphate prescribing (25%). 57 patients had PPH > 1.5 L. Measures with 100% compliance were: the ‘ABC’ cheque, administering IV fluids and measuring FBC. Weighing blood loss, establishing intravenous access and administration of high-flow oxygen and warmed fluids (32.4%-54%) need to be performed more often.

Conclusion Many aspects of the guidelines are adhered to, but areas of concern must be improved in order to optimise patient care and outcome.

PM.16 ULTRASOUND COLOUR-FLOW DOPPLER IN INITIAL ASSESSMENT OF MORBIDLY ADHERENT PLACENTA FOLLOWED BY SELECTIVE MR IMAGING: A CASE SERIES

doi:10.1136/archdischild-2013-303966.101

LJ Scarrott, OA Jibodu, U Rajesh. York Teaching Hospital, York, UK

Morbidity adherent placenta (MAP) is the abnormal attachment of the placenta to the uterine wall in which trophoblastic cells invade the uterine tissues. MAP is rare, affecting 1 in 2500 pregnancies, however it is associated with high fetomaternal morbidity and mortality. Previous caesarean section is a major risk factor for development of MAP, and complicates 24% of cases of placenta praevia after one prior caesarean section. With the current trend of increasing caesarean section rates, MAP will pose significant obstetric problems in the future.

Antenatal diagnosis of MAP has been shown to reduce maternal morbidity. Recent guidance from the National Institute for Clinical Excellence suggests that in cases where there is suspicion of MAP, colour-flow Doppler ultrasound should be used as a first line diagnostic tool. Presence of irregular lacunae within the placental architecture and loss of the clear space in the retroplacental plane is considered to be useful diagnostic criteria in ultrasound imaging of MAP. Where such ultrasound changes are found, magnetic resonance imaging (MRI) can then be considered to confirm diagnosis and evaluate the extent of invasion which would aid management planning.

We present a case series of 6 patients presenting to York Teaching Hospital in whom MAP was queried on the basis of previous caesarean section, placental localisation scan or clinical presentation. We discuss the role of colour-flow Doppler ultrasound in the initial assessment of suspected MAP followed by selective use of MRI.

PM.17 IMPACT OF MATERNAL OBESITY ON ACCURACY OF SONOGRAPHIC FETAL WEIGHT ESTIMATION IN IUGR

doi:10.1136/archdischild-2013-303966.102

F Cody, J Unterscheider, S Daly, MP Gentry, MM Kennelly, FM McAuliffe, K O’Donoghue, A Hunter, JJ Morrison, G Burke, P Dicker, EC Tully, FD Malone. Perinatal Ireland Research Consortium, Dublin, Ireland

Objective The objective of this analysis, as part of the multicentre prospective PORTO Trial, was to determine whether increasing maternal BMI decreases the accuracy of sonographic fetal weight estimation in IUGR pregnancies.

Study design The PORTO Trial recruited 1,118 consecutive ultrasound-dated singleton IUGR pregnancies, defined as EFW < 10th centile. Maternal BMI was recorded at booking and divided into 4 subcategories. Accuracy of fetal weight assessment was defined as difference between EFW within 2 weeks of delivery and actual birthweight.

Results Of the 1,076 recruited patients with complete records, 693 (64%) were of normal weight (BMI < 25), 256 (24%) were overweight (BMI 25–30), 93 (9%) were obese class 1 (BMI 30–35) and 32 (3%) were obese class II (BMI 35–40) (Table 1). Overall, fetal weight estimation prior to delivery was within 6% of respective birthweight. EFW was not influenced by increasing maternal BMI and EFW accuracy was only marginally better in normal weight mothers. Greater BMI was associated with earlier gestational age at delivery.

Conclusion These data show that ultrasound is reliable in the assessment of fetal weight in IUGR in the presence of increased maternal BMI.

PM.18 MATERNAL RESTING PERIPHERAL BLOOD FLOW AND TISSUE OXYGENATION IN PREGNANCIES COMPLICATED WITH PRE-ECLAMPSIA AND IUGR

doi:10.1136/archdischild-2013-303966.103

Background Pre-eclampsia is characterised by hypertension and proteinuria and associated with systemic hypoperfusion of multiple maternal organs. Intrauterine growth restriction (IUGR) is a recognised complication of pre-eclampsia and the two conditions
share the same primary pathology. The clinical features of pre-eclampsia are consistent with hypoxia and the changes in oxygen delivery and consumption indices in women with severe disease are similar to that observed in distributive shock. However, so far there are no studies done on maternal tissue oxygenation levels in pregnancies complicated by pre-eclampsia and IUGR.

**Methodology** Women in their third trimester with pre-eclampsia, IUGR and normal pregnancy (n = 16, 6, 16 respectively) were recruited for the study. Filtrass strain gauge plethysmography was used to compare calf blood flow and Mediapi pulse oximeter was used to compare the oxygenation in the three groups.

**Results** The resting peripheral blood flow was significantly reduced in pre-eclampsia group compared to normal pregnancy group (mean ± SEM [2.1 ± 0.22 vs.1.01 ± 0.1], p = 0.003), however no change was demonstrated in IUGR group compared to normal pregnancy group (mean ± SEM [2.1 ± 0.22 vs.1.9 ± 0.5], p = 0.92). No significant difference was noted in maternal tissue oxygenation between the normal pregnancy, pre-eclampsia and IUGR groups (mean ± SEM [97.13 ± 0.4, 96.69 ± 0.53, 97.83 ± 0.47 respectively]) p = 0.26). No correlation was found between blood flow and tissue oxygenation.

**Conclusion** This study demonstrated that there is reduced resting peripheral blood flow in women with pre-eclampsia but not in IUGR and the reduction in blood flow in pre-eclampsia is not associated with changes in tissue oxygenation.

**PM.20 THYROID HORMONE ACTION IN THE DECIDUA DURING HUMAN PREGNANCY**

doi:10.1136/archdischild-2013-303966.104

1Vasilioulou, LS Loubiere, GE Lash, D Ohiuza, JA Franklin, MD Kilby, SY Chan. University of Birmingham, Birmingham, UK; 2Newcastle University, Newcastle-Upon-Tyne, UK; 3Walsall Hospitals NHS Trust, Walsall, UK

**Introduction** Maternal thyroid dysfunction is associated with complications of placental inclusion and miscarriage and pre-eclampsia. We hypothesise that thyroid hormones (TH) play an important role within human decidua in regulating placentation.

**Methods** Decidua from human pregnancy were obtained from 1st (8–11 weeks) and 2nd trimester (12–20 weeks) surgical terminations in the UK. Immunohistochemistry showed the expression TH transporters (MCT8, MCT10) and receptors (TRα1, TRβ1) required for TH-responsiveness in uNKs and macrophages from early gestation. The viability of TDC and cell isolates were unaffected by T3. In 1st trimester, T3 reduced IL-10 secretion by TDC and CD10+ve cells (p < 0.01), and reduced GM-CSF, IL-10, IL-1β, IL-6, MCP-1 by macrophages (p < 0.01). In 2nd trimester, T3 increased IL-10 by TDC (p < 0.01) and reduced IL-10 by uNKs (p < 0.001). T3 increased VEGF secretion by 1st trimester uNKs (p < 0.05), and angiopoietin-2 by 2nd trimester TDC and uNKs (p < 0.05). Conditioned media from T3-treated TDC and macrophages did not alter EVT invasion compared to untreated controls.

**Conclusion** TH regulate decidual cytokine and angiogenic growth factor secretion in a cell-specific and gestation-dependent manner. The summation of TH effects upon the secretome do not affect EVT invasion.

**PM.21 COMPLIANCE WITH POSTNATAL THROMBOPROPHYLAXIS**
doi:10.1136/archdischild-2013-303966.105

1F Ayim, DO Banfield, JC Garling, 2Page. Imperial College London, London, UK; 2West Middlesex University Hospital, Middlesex, UK

**Background** Venous thromboembolism (VTE) is the 3rd leading cause of maternal death in the UK. In order to minimise VTE risk in the postnatal period, we introduced a new scoring system in June 2011, based on RCOG guidelines. Every woman’s VTE risk is scored, and those who meet predetermined criteria are discharged on a seven days (7/7) or six weeks (6/52) course of low molecular weight heparin (LMWH). There were concerns regarding patient compliance and so a survey was conducted to explore this.

**Method** Pharmacy data identified 113 postnatal women who were discharged in November 2011 on LMWH. A telephone survey in February 2012 assessed understanding of the need for LMWH, and compliance.

**Results** 52 women were successfully contacted: 29 had been prescribed a 7/7 course, and 23 a 6/52 course.

- 100% of women understood the need for LMWH.
- 96% of those on a 7/7 course completed all injections.
- Only 52% completed the 6/52 course.

We identified reasons for non-compliance and the destination of unused LMWH.

**Conclusion** Non-compliance has implications for both patient safety and cost. The survey highlighted the importance of effective patient education and identified a need for improved communication between primary and secondary care. A multidisciplinary approach, with all healthcare professionals emphasising the importance of LMWH in the postnatal period may improve long-term compliance. A patient information leaflet has since been introduced.

**PM.22 THE ROLE OF VEGF in TROPHOBLAST SURVIVAL – IMPLICATIONS FOR PRE-ECLAMPSIA PATHOPHYSIOLOGY**
doi:10.1136/archdischild-2013-303966.106

1VL Bills, 2DO Bates, PW Soothill, 3TD Overton. 1St Michael’s Hospital, Bristol, UK; 2Microvascular Research Laboratories, University of Bristol, Bristol, UK

It is widely accepted that the pathophysiological foundations of pre-eclampsia are laid down in the first trimester, with inadequate invasion of placental trophoblasts into maternal spiral arteries of the uterus, resulting in defective arterial remodelling. The angioenic VEGF family of glycoproteins are expressed in first trimester trophoblasts and are important factors in placental development, which occurs in a hypoxic (<2% O2) environment up to 10–12 weeks and normoxia (>20% O2) thereafter. First trimester VEGFα levels are low in women destined to later develop pre-eclampsia, so we investigated whether VEGFα plays a role in early trophoblast survival and therefore pre-eclampsia pathophysiology.

Trophoblast cells were cultured in hypoxic and normoxic environments, in the absence and presence of VEGFα and a VEGFα blocking antibody clone 56–1. Cell survival was studied via cytotoxicity experiments. Production of VEGFα by trophoblasts was determined via enzyme linked immunosassay (ELISA). VEGFα production by trophoblasts was increased in response to hypoxia (hypoxia: 1812 ± 33 pg/ml vs. normoxia: 1407 ± 95 pg/ml, unpaired t test, p = 0.016), and inhibition of VEGFα increases
