Background A meta-analysis of 27 studies demonstrated that cervical surgery for cervical intraepithelial neoplasia (CIN) was associated with almost two-fold increased risk of preterm birth (PTB). A more recent epidemiological study has suggested no influence of cervical surgery on risk of PTB. However, rates of intervention were not analysed. The aim of this study was to determine the impact of cervical surgery on intervention and pregnancy outcome in high-risk asymptomatic women.

Methods Analysis of 535 women attending preterm surveillance clinic at St. Thomas’ hospital (1997 to 2011) with a history of one or two previous PTB/mid trimester loss. The rates of spontaneous preterm delivery (<37 weeks) and interventions were compared in women with and without destructive cervical surgery (DCS).

Results Previous cervical surgery did not significantly increase the risk of a further PTB (13/47 [28%] with history of DCS vs. 122/488 [25%] with no history of DCS, p = 0.68). Women that had previous DCS were significantly more likely to require an ultrasound indicated cерcleage compared to those that had no history of DCS (9/47 [19%] vs. 48/488 [10%] respectively; p < 0.05).

Conclusion In this high-risk cohort, DCS increases the risk of intervention, but not the risk of subsequent PTB. Reports suggesting treatment is not a risk factor need to include effects on intervention. This suggests that cervical surgery may be detrimental to the mechanical function of the cervix and further research to define the role of cерcleage in women with prior PTB and DCS is warranted.

Conclusion Asymptomatic high-risk women with cervical cerclage in situ may have more false positive fFN test than women with an abdominal cerclage. Quantitative fFN is an accurate predictor of PTB in women with abdominal cerclage.

<td>TRANSFORMATION FROM 11 – 19 WEEKS GESTATION</td>
</tr>
</tbody>
</table>

Background Uterine spiral artery (SpA) remodelling, characterised by loss of vascular smooth muscle (VSM), is essential for successful placentalation; impaired SpA remodelling occurs in late miscarriage, pre-eclampsia and fetal growth restriction. Non-remodelled and completely remodelled SpA are easily identified histologically but identification of partially remodelled SpA is less defined; various stages have been proposed based on semi-quantitative scoring. The aim was to compare semi-quantitative scoring of VSM loss with quantification of VSM.

Methods Placental bed biopsies from women undergoing surgical pregnancy termination were immunostained to assess trophoblast (cytokeratin 7), endothelial cells (factor 8), myometrium and VSM (α-smooth muscle actin). SpA VSM was scored using 4 categories: SM1 = intact but separated; SM2 <50% lost; SM3 = 50–90% lost; SM4 >90% lost. 20 SpA were independently scored by 2 individuals who showed >95% concordance. VSM was also quantified using a computerised pixel counting (using Adobe Photoshop).

Results VSM loss was scored in 175 SpA (11–19 weeks gestation) in decidua, junctional zone and myometrium; SM1 = 47, SM2 = 24; SM3 = 35; SM4 = 69. The 4 categories of VSM loss correlated to the quantified VSM loss (analysis of variance P = 0.001); differences in VSM % based on pixel counts between groups were confirmed with t tests: mean, standard deviation. SM1 76.76, 12.12; SM2 62.46, 13.03; SM3 38.50, 16.51; SM4 11.28, 12.69; P < 0.001 all cases.
Conclusion  Assessment of SpA remodelling may not require quantitative assessment since semi-quantitative scoring correlates well with quantified VSMC in partially remodelled SpA. This scoring technique provides an approach to assessment of uterine SpA remodelling in pregnancy pathology.

**PM.27** GESTATIONAL DIABETES: IS IT SAFE NOT TO INDUCE?
doi:10.1136/archdischild-2013-303966.110

Background  Despite recent advances in the management of Gestational Diabetes (GDM), there is a paucity of evidence addressing the ideal timing of delivery in women who are well controlled. If recent proposed changes to diagnostic criteria were to be adopted, the incidence of GDM would increase up to 16%. This could potentially increase induction and caesarean section rate.

Objective  To assess the safety of not routinely inducing well controlled gestational diabetic women at 38 weeks.

Methods  Retrospective study in a district general hospital.

Outcomes  Incidence of fetal macrosomia, stillbirth, caesarean section, shoulder dystocia, third degree tear, postpartum haemorrhage (PPH) and admission to SCBU in this population.

Results  In 2012, 157 women were diagnosed as GDM according to WHO/NICE criteria; 47% were treated with Metformin and 15% with Insulin. 48 women, well-controlled on diet, or Metformin, and/ or Insulin, were allowed to go into spontaneous labour. 12 of these women were eventually induced for post-maturity.

The incidence of macrosomia, emergency caesarean section, third-degree tear, PPH, SCBU admission was 4%, 12.5%, 4%, 4% and 4% respectively. There were no cases of shoulder dystocia or stillbirth. These figures are well below the national average.

Conclusion  Treating well-controlled gestational diabetics conservatively at term is a safe management option.

**PM.28** AUDIT ON CARE AND OUTCOME OF PREGNANCY IN WOMEN WITH MORBID OBESITY
doi:10.1136/archdischild-2013-303966.111
D Kapoor, J Davison, S Rajendran. Royal Derby Hospital, Derby, UK

Background  Obesity is one of the biggest challenges facing maternity services today. Women with obesity have significant higher complication rates and these can potentially be reduced with good quality clinical care.

Objectives  To compare current practise at Royal Derby Hospital with the RCOG/CEMACE guideline on management of pregnant women with morbid obesity.

Methods  A retrospective case-note audit of all women delivered at RDH between 01/09/2011 and 31/08/2012 with booking BMI ≥ 40.

Results  There were 6252 deliveries at RDH with 140(2.24%) patients with BMI ≥ 40. We analysed 134 case notes. Glucose tolerance test was performed in 96.2% of patients at 28 weeks gestation and 55.2% had an anaesthetic review. 47.1% of women laboured spontaneously, 36.5% of labours were induced and 16.4% had elective caesarean section (CS). 67.8% of women had a normal vaginal delivery, the instrumental delivery and Emergency CS rate were 9.0% and 23.2% respectively. 89.6% of operative deliveries were either performed or supervised by ST6 and above. 96.2% had active management of 3rd stage and major postpartum haemorrhage occurred in 8.2% of women. For term deliveries the birth weights ranged from 2620 g to 5080 g (21.6% greater than 4000 g). 47.3% had postnatal thromboprophylaxis with 81.4% on sufficient thromboprophylaxis for weight.

Conclusion  The audit demonstrated that the guidelines were not being adhered to, particularly for anaesthetic assessment and venous thromboembolism risk. Review of our local guideline with more training for healthcare professionals involved in the care of this group of high risk patients is required to improve maternal and neonatal outcomes.

**PM.29** COMPARISON OF HEPATIC PERFUSION BETWEEN PRE-ECLAMPSIA AND NORMAL PREGNANCY
doi:10.1136/archdischild-2013-303966.112
A Anbazhagan, S Ong. Royal Jubilee Maternity Hospital, Belfast, UK

Objective  We wanted to provide evidence for or against the thus far, unaccepted theory that the genesis of pre-eclampsia arises from the maternal venous circulation. We also wanted to assess hepatic perfusion in pre-eclampsia using 3 dimensional ultrasound.

Methods  We measured hepatic portal vein flow in 12 women with normal pregnancy and 11 women with pre-eclampsia using standard Doppler ultrasound. We evaluated the three dimensional (3D) indices of hepatic perfusion: flow index (FI), vascular index (VI) and vascularisation flow index (VFI) which are believed to reflect vascularity and flow intensity. Because of small numbers, a non-parametric test was used to test differences between groups.

Results  Hepatic portal vein flow was not different between women with normal pregnancy compared to women with pre-eclampsia [228.1 (215.5–270.6) vs. 283.0 (145.9–344.6); p = 0.90]. The 3D indices of hepatic perfusion were as follows [FI; 36.3 (30.7–42.5) vs. 39.7 (27.7–44.2), p = 1.00; VI; 11.7 (3.6–21.2) vs. 3.0 (0.5–7.6), p = 0.00; VFI; 4.7 (1.2–8.3) vs. 1.2 (0.1–3.2), p = 0.06 respectively].

Conclusion  We were not able to provide evidence in support of the suggestion that the genesis of pre-eclampsia arises from the maternal venous circulation. Because of the wide variability of our data, overall we conclude that there is no difference in the 3D indices of hepatic perfusion in women with pre-eclampsia compared to normal pregnant women.

**PM.31** A LITERATURE REVIEW OF INTERFERON BETA TREATMENT IN MULTIPLE SCLEROSIS PATIENTS DURING PREGNANCY – IMPLICATIONS FOR FUTURE RESEARCH
doi:10.1136/archdischild-2013-303966.113
SK Carney, Y Igzeer. Pennine Acute Trust, Oldham, UK

Multiple sclerosis is a neurological disease caused by discrete plaques of demyelination at sites throughout the central nervous system caused by a T-Cell mediated immune response with an unknown trigger. It has a lifetime risk of 1:1000 in the UK, and is twice as prevalent in females with the typical onset being between 20 and 40 years of age, namely the childbearing ages.

There are many disease-modifying therapies used to treat Multiple Sclerosis. However, immunomodulatory and immunosuppressive drugs used at any stage of pregnancy may affect fetus formation and/or development.
