Conclusion Placental examination serves several vital roles in babies born with suspected HIE: it defines pathophysiology, provides important prognostic information regarding future neurodevelopmental outcome, and shows mitigating factors of medicolegal relevance to causation of brain injury. Intrapartum infection and chorioamnionitis are associated with poor neonatal outcomes including cerebral palsy. Only 30% placentas were examined in our tertiary centres, yet those examinations showed a high incidence of chorioamnionitis. The low rate of placentas being submitted for examination in neonates born depressed, coupled with the high incidence of proven chorioamnionitis in those submitted, is of great concern.

Objective To study the association between travel time from home to hospital on intrapartum stillbirth and neonatal mortality.

Population All births to women who were resident in Wales between 1995–2009 (n = 498,052).

Outcome Measures Intrapartum stillbirth, early and late neonatal mortality.

Methods We calculated the travel time to all hospitals with maternity services based on the grid reference for postcode of mother’s place of residence at the time of birth. We used logistic regression to obtain odds ratios for the association between travel time and outcome, adjusted for maternal age, parity, Townsend score for social deprivation and urban/rural location.

Results There were 412,827 singleton births during the study period. The intrapartum stillbirth rate was 0.3 per 1,000 (n = 135); early neonatal death rate 1.5 per 1,000 (n = 699) and late neonatal death rate 0.6 per 1,000 (n = 251). The median travel time to place of birth was 17 minutes IQR (11, 27), and the median distance travelled was 11.7 km. The risk of early neonatal death increased with travel time of at least 45 minutes to place of birth (adjusted OR 1.7 95% CI 1.2, 2.5). In order to explore whether or not birth outcomes were associated with location of maternity services we repeated the analysis using travel time from home to nearest hospital with maternity services and found no association.

Conclusion Although the risk of adverse birth outcomes is increased with longer travel times to the place of birth this is not explained by distance to the nearest hospital with maternity services.

Introduction Preterm birth is the leading cause of neonatal morbidity and is associated with increased rates of operative delivery. Little is known about the impact of preterm caesarean section on mode of delivery and outcome in subsequent pregnancies.

Aim To determine the impact of preterm caesarean section in primips and multipus on mode of delivery and obstetric outcome in subsequent pregnancies.

Study design We designed a retrospective review of all deliveries in the Rotunda Hospital from January 1st 2000 to December 31st 2005. All preterm deliveries (less than 37 weeks gestation) were identified and those requiring caesarean delivery formed the study cohort. All cases with previous operative deliveries were excluded and the remaining cases were reviewed for outcome in subsequent pregnancies.

Results There were 879 preterm caesarean sections during the study period representing 6.6% of all sections over the study period (879/13336).

In total 672 (76.4%) met the inclusion criteria and of these 408 (60.8%) went on to have a further delivery in the hospital. Preterm caesarean section was associated with a vaginal delivery rate of 32 to 44 percent in subsequent pregnancies. There is associated increased neonatal morbidity contributed to primarily by the high incidence of preterm birth in subsequent pregnancies (22.34%). There were also 3 neonatal deaths in subsequent pregnancies in the cohort.

The overall classical caesarean section rate was six percent and there was one caesarean hysterectomy in our cohort.

Conclusions Preterm caesarean section is associated with adverse fetal outcome in subsequent pregnancies.

PP44 STRESS IN EARLY PREGNANCY IN THE AETIOLOGY OF GASTROSCHISIS: AN INCIDENT CASE CONTROL STUDY

doi:10.1136/archdischild-2013-303966.324

A Evans, S Paranjothy, S Palmer. Cardiff University, Cardiff, UK

Introduction Maternal stress is associated with increased risk of spina bifida and anencephaly. We investigated the effect of major stressful life events in the first trimester on risk of gastroschisis, accounting for the mediating effects of social support and known risk factors such as cigarette smoking, low body mass index and poor nutrition.

Method We analysed data from an incident case control study of pregnant women resident in five UK regions between 01.07.2007 and 28.02.2010. Three controls were recruited for each case. Major stressful life events and social support were assessed using questions from several validated assessment tools, during interviews in the antenatal period. Logistic regression was used to obtain odds ratios for the association between maternal stress and risk of gastroschisis.

Results During the study period, 124 gastroschisis cases were identified by collaborating centres. 75% of cases (n = 91) and 70% of controls (n = 217) were recruited. In the multivariable model including social class of the mother, cigarette smoking, alcohol consumption, body mass index, folic acid and fruit and vegetable consumption, major stressful life events had an independent effect on the risk of gastroschisis (aOR 4.9 95% CI 1.2,19.4). Moving house in first trimester was also an independent risk factor (aOR 4.9 95% CI 1.7,19.9). Lack of social support was found to be a partial mediator for stress.

Conclusion These findings provide new evidence that maternal stress plays a role in the aetiology of gastroschisis, possibly through increased production of corticosteroids that have been shown to be teratogenic in animal models.

PP46 WHAT INFLUENCES A PARENT’S DECISION-MAKING FOR PERINATAL AUTOPSY? A QUALITATIVE INVESTIGATION

doi:10.1136/archdischild-2013-303966.326

1S Meaney, 1S Gallagher, 1JE Lutomski, 1K O’ Donoghue. 1National Perinatal Epidemiology Centre, University College Cork, Ireland; 2Dept of Psychology, University of Limerick, Ireland; 3Dept. of Obstetrics and Gynaecology, University College Cork, Ireland

Introduction Autopsy findings provide valuable information on cause of perinatal death and are the cornerstone for research and audit. However, delivery of autopsy services is sometimes at odds with parental wishes and legal requirements.

Objectives This study aims to gain insight into parents’ perception of autopsy and the decision-making processes.

Conclusion These findings provide new evidence that maternal stress plays a role in the aetiology of gastroschisis, possibly through increased production of corticosteroids that have been shown to be teratogenic in animal models.

Abstracts

**Study design** A qualitative semi-structured interview format was utilised. Purposive sampling was used to recruit 10 parents who either consented or declined autopsy from a large hospital, where there were 30 stillbirths in 2011. Interpretative phenomenological analysis (IPA) was employed as the analytic strategy. IPA allows for close examination of parents’ experiences using a small purposive sample by identifying superordinate themes which highlight what is important to the participant but also detail the meaning of these phenomena in a social context.

**Results** Findings revealed four superordinate themes influencing parents’ decision-making: attribution of death, searching for meaning, knowledge of the autopsy procedure and protective parent. Parents discussed the need for the certainty of the diagnosis as it influenced emotional reactions including difficulty in coping with the uncertainty of the outcome of a future pregnancy. Parents, who declined autopsy, strongly indicated that the key reason was to protect their child from further harm. Parents’ knowledge and understanding of the autopsy process was acquired primarily from public discourse, with particular reference to television programmes, which elicited negative responses from parents due to their perception of the invasive nature of the autopsy process.

**Conclusion** These findings have implications for psychological models of decision making and clinical practice. This study underscores the challenges that clinicians face in overcoming public misperceptions of the invasiveness of some autopsy procedures.

**EVALUATING OUTCOMES OF SKELETAL DYSPLASIAS (SDS)**

**Objective** To evaluate the outcome of 543 pregnancies identified with a skeletal dysplasia or an antenatally suspected skeletal anomaly in the East Midlands and South Yorkshire (EMSYCAR) Congenital Anomaly Register over a fifteen year period.

**Background** Skeletal dysplasias form a large group of congenital anomalies affecting cartilage and bone growth. Strongly associated with syndromes and underlying genetic conditions, they vary in severities from lethal achoondroplasias to milder osteochondroplasias. The UK Fetal Anomaly Screening Programme antenatal detection target for lethal SDs is 60%. Given the problems with definitive antenatal diagnosis this is difficult to achieve.

**Methods** Between 1997 and 2011, 982,073 births were monitored by EMSYCAR; 543 cases were identified with a SD or antenatally suspected skeletal anomaly (a birth prevalence of 5.53/10,000 births). Each case was individually reviewed to ascertain the type and severity of the skeletal anomaly as ICD-10 codes alone cannot adequately perform this function.

**Results** 62 (11.4%) of the 543 had fully resolved by delivery. 77 (18.4%) resulted from a chromosomal anomaly, and 65 (12.0%) had other structural anomalies. The remaining 359 (62.4%) had a skeletal anomaly (3.45/10,000), of which 206 had a SD. Of these 77 were non-lethal and 129 lethal (1.31/10,000). Overall, 93% of lethal SDs were identified antenatally, 65% within the FASP screening window (<20+6 weeks gestation).

**Conclusion** Although only 38% of total cases had an isolated actual or suspected skeletal anomaly, almost two-thirds of those were lethal SDs. The vast majority were antenatally diagnosed and the FASP target achieved.

**PERINATAL OUTCOMES IN TWIN PREGNANCY IN IRELAND**

**Introduction** Over the past two decades multiple births have been increasing in Ireland, in 2011 17.9 sets of twins per 1,000 live births were born. This study aims to investigate adverse perinatal outcomes in twin pregnancies.

**Methods** A retrospective cohort study of all twin pregnancies delivered from 2009 to 2011 in a large, tertiary hospital (~8,000 deliveries per annum) in the Republic of Ireland was conducted. Birth registers, NCIU and clinic records were reviewed to examine perinatal outcomes.

**Results** Of the 523 twin pregnancies included in the study mean gestational age at delivery was 35.1±3.8 (weeks). 79.1% (n = 415) delivered preterm (<37 weeks) of which 75.8% (n = 315) were classified as late preterm infants, delivering between 34–37 weeks. Among the 523 twins 47.5% (n = 247) were nulliparous and 16.3% (n = 87) were monochorionic (MC). Nulliparity and MC were both significantly associated with preterm delivery (p = 0.02 and p < 0.001, respectively). Both had lower mean gestational ages (p = 0.007 and p < 0.001, respectively) with significant lower birth weights (p < 0.001) compared to parous and dichorionic (DC) pregnancies. Intra-uterine fetal death (11.9% vs. 1.3%; p < 0.001), TTTS (24.1% vs. 0.1%; p < 0.001) and perinatal mortality (p = 0.002) were higher in MC pregnancies compared to DC. Mean maternal age was 33.2 ± 4.9 years and fetal anomalies increased with advanced maternal age; <40 years of age, (p = 0.01).
